Introduction

Two-spotted spider mite (TSSM), *Tetranychus urticae* (Koch), is a chelicerate herbivore with an exceptionally wide host range. It is a frequent pest of a wide variety of economically important crops.

While low-level infestations are controlled by biological agents such as beneficial predatory mites, midges, and bugs, chemical controls are regularly implemented against persistent pest populations. However, pesticide resistance is frequently reported in *T. urticae* populations across the globe.

Materials and Methods

Here we present a 2021 assessment of pesticide resistance of *T. urticae* populations from Southwestern Ontario. Mite populations were collected from a variety of crops (cucumber, pepper, strawberry, tomato, and soybean), and production systems (greenhouse and field). Mite resistance was assessed against following active compounds: abamectin, bifentazate, cyflumetofen, dimethoate, etoxazole, pyridaben, and spiromesifen.

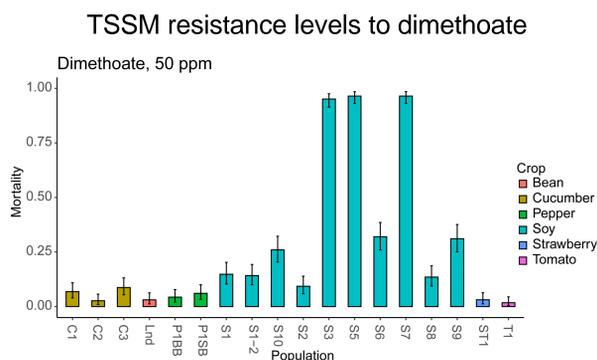

We used two types of bioassays, depending on the mode of action of the analyzed pesticides:

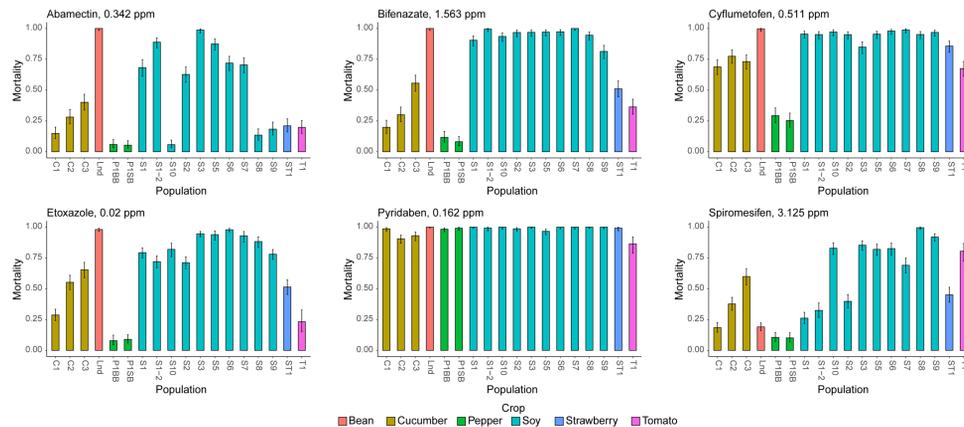

- High throughput soaking-based protocol (adulticidal), to assess mite mortality;
- Traditional leaf disk dipping protocol (ovicidal and adulticidal), to assess mite egg mortality or adult female mite fecundity.

Results

Dimethoate is the only registered pesticide for soybeans in Ontario. 7/10 mite populations collected from soybean and all greenhouse populations were resistant to dimethoate.

TSSM resistance levels to pesticides used in greenhouses

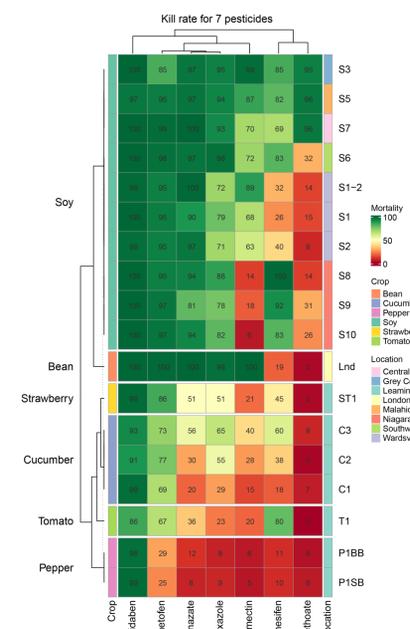

We have considered mortality rate at or below 40% as a resistance threshold. At this kill rate threshold only 3/17 populations were fully susceptible to tested compounds.

Our results indicate that resistance to multiple pesticides was present in the majority (13/17) of the sampled populations, with the greenhouse-collected populations being the most resistant.

Soybean collected populations demonstrated frequent resistance to dimethoate (7/10). A few soybean populations were also resistant to abamectin (3/10) and spiromesifen (3/10).

All tested greenhouse populations showed high resistance levels to the majority of tested pesticides apart from pyridaben.

Summary heatmap of determined mortality levels in collected *T. urticae* populations grouped by crop and subsequently clustered by the degree of response similarity.

Conclusions

Our assessment may inform a choice of additional pesticide registration for spider mite control on soybean, considering that dimethoate has limited effectiveness.

Bifenazate, cyflumetofen, etoxazole, and pyridaben could be potential new products to be registered for the soybean crop.

These results may be used to prioritize and plan pesticide usage on crops where multiple products are registered.

We are continuing this survey with 40 TSSM populations collected in Southwestern Ontario in Summer of 2022.
