### Introduction

- Since the legalization of cannabis in 2018 fungal pathogens have been significantly undermining cannabis yield, with losses as high as 30%<sup>1</sup>
- Furthermore, fungal pathogens in cannabis can infect humans if not managed correctly by producing mycotoxins which can result in fever, pneumonia, and neutropenia<sup>2,3</sup>
- Fungal pathogens are often very difficult for growers to manage due to the lack of registered fungicides available for use on cannabis<sup>1</sup>
- Additionally, fungicide residue on cannabis can be detrimental to human health as it has been shown to contain endocrine disruptors and hepatotoxic compounds<sup>3</sup>
- *Bacillus amyloliquefaciens* (I113), a biocontrol agent, offers a promising solution to reduce fungal infections in cannabis due to its strong antifungal metabolite production
- From previous trials I113 is known to inhibit *Fusarium*, *Alternaria*, *Colletotrichum*, *Septoria* and *Botrytis* fungal species, all of which are common fungal pathogens in cannabis
- I113 has also shown to be an effective bio-stimulant in other field trials with crops such as squash, pumpkins, and tomatoes

### Objectives

- To identify the most common fungal pathogens affecting outdoor cannabis production where the trial was conducted
- To determine the *in vitro* anti-fungal activity of I113 against common fungal isolates found in cannabis
- To determine the biocontrol capabilities of I113 on fungal pathogens in cannabis grown outdoors

### Methods

#### Inhibition Assays

- A colonization assay was performed to determine the fungal pathogens that had infected this crop of cannabis
- Fungi were isolated and identified by sequencing
- Fungal isolates were plated on 1:1 PDA-NA and grew until they reached a diameter of ~3cm
- 10µL of I113 along with an NB control were plated on opposite sides of the fungal isolates

#### Metabolite Screening

- Metabolites were harvested from I113
- High Performance Liquid Chromatography (HPLC) was used to identify metabolites

#### Field Trial

- I113 was inoculated in nutrient broth and grown for 48 hours on a shaker at 150 rpm and 30°C
- Culture was diluted to 3% and sprayed weekly from June 20<sup>th</sup>, 2023, to August 18<sup>th</sup>, 2023
- Disease scores were recorded weekly from August 1<sup>st</sup>, 2023, to September 9<sup>th</sup>, 2023, using a scale of 1-4

### Results

#### Inhibition Assays

- *Fusarium*, *Phoma*, *Sarocladium*, and *Trametes* fungal species were found to be the main fungal pathogens infecting this crop of cannabis
- I113 is a good biocontrol agent (**Table 1**) as it shows strong inhibition towards *Fusarium*, and moderate inhibition towards *Phoma* and *Trametes* (**Figure 1**)
- I113 produces antifungal metabolites to inhibit the growth of fungal pathogens (**Table 2**)

| Functional Traits           | I113    |
|-----------------------------|---------|
| <i>Fusarium</i> Inhibition  | ++++    |
| <i>Phoma</i> sp.            | +       |
| <i>Sarocladium strictum</i> | Unknown |
| <i>Trametes versicolor</i>  | ++      |

**Table 1. Functional; traits of I113.** Scoring scale: (-) negative, (+) weak positive, (++) positive, (+++) high positive, (++++) strong positive.

| Metabolite | Mode(s) of Action  |
|------------|--|
| Fengycins  | Induced systematic resistance<br>Membrane pore formation |
| Surfactins | Induced systematic resistance<br>Membrane pore formation |
| Iturins    | Membrane Pore Formation                                  |

**Table 2. Mode of action of 3 cyclic lipopeptides produced by I113<sup>4</sup>.** Responsible for the antifungal properties of I113.

**Figure 1. Inhibition assays plates with cannabis isolates and I113.** Qualitative analysis of assays determined I113 functional traits.

*F. graminearum*

*Phoma* sp.

*T. versicolor*

### Field Trial

- 40% of fungal isolates from this crop of cannabis were *Fusarium*, the next most abundant fungal pathogen only comprised 10% of the isolates
- I113 reduced disease by an average of 38% during the cannabis vegetative stage with 49% of treated plants having a healthy disease score (**Figure 2&3**)
- Through the vegetative stage to the end of the pre-flowering stage, I113 reduced disease by an average of 28% with 37% of treated plants having a healthy disease score (**Figure 2**)
- Over the whole growing season I113 reduced disease by an average of 20% (**Figure 2&3**)
- The disease characteristics did not vary significantly between the control and treated replicates

**Figure 2. Comparison of disease in control and treated cannabis plants.** (Top) 6 weeks after treatment began (Bottom) 2 Weeks after budding started.

**Figure 3. Ratio of healthy (2 or under, dark green) to unhealthy (3 or over, light green) disease scores.** (A) Vegetative stage (B) Vegetative and pre-flowering stage (C) Entire growing season.

### Conclusions

- The most common fungal pathogen in this crop of cannabis is *Fusarium* with the most common species being *Fusarium equiseti*
- *In vitro* I113 is effective at inhibiting common fungal pathogens such as *Fusarium*, while still moderately inhibiting less common pathogens such as *Phoma* and *Trametes*
- I113 was effective at reducing disease incidence and severity in cannabis plants
- As the growing season progressed treated plants became increasingly more diseased

### Future Directions

- Confirm the effectiveness of I113 at suppressing fungal pathogens in cannabis, specifically how to reduce pathogens near the end of the growing season
- Continue to build a database of common fungal pathogens in cannabis to ensure the application of biocontrol treatments targets the most plentiful and harmful pathogens
- Explore the possibility of I113 working as a bio-stimulant in cannabis
- Run trials to determine if I113 could act as either a biocontrol agent or bio-stimulant in closely related crops such as hemp or hops
